

Immediate implantology is a simple implantation system with many advantages. This treatment method requires almost no jaw bone. The implants can be loaded shortly after the operation. They can even be used on patients who are not suitable for conventional implantation techniques.

The method and implants developed in Switzerland are between 8 mm and 55 mm long and have a diameter of just 3 mm to 12 mm. This means that they can be perfectly adapted to the bone available to each patient. Painful, time-consuming and costly bone augmentation (sinus lift procedures) is therefore a thing of the past. This accelerates the treatment and finally makes it affordable.

The design of the implants allows them to be placed where the bone is. Independent of the tooth position! This modern, efficient, fast, inexpensive and sustainable treatment method has revolutionized dentistry world

Brief overview of basal implantology:

- without painful, time- and cost-intensive bone augmentation
- without months of healing phase
- immediately resilient teeth
- Treatment duration max. 5 days
